

Three-Dimensional Molecular Dynamics Simulation: with Verlet algorithm

Tridip Das

March 18, 2015

Abstract

The study of classical Molecular Dynamics investigates the interaction of atoms in a face centered cubic (FCC) lattice at different temperature. For this study Newton's law of particle interaction has been applied with Verlet algorithm for velocity calculation. The potential interactions are described with Lennard-Jones pair potential. For initialization of velocity Box-Muller method is used. The particles are interacted in periodic boundary condition. 32 atoms are taken for all the studies described, which is sufficient to adequately describe the system. The temperature effect on lattice is studied with observation of melting phenomena. For ease of calculation scaled parameters are used in this study.

1 Introduction

The study of Molecular Dynamics (MD) investigates the interaction and motion of atoms/molecules in a many body simulation. The concept of MD applicable in wide area of sciences. Though there are two types of MD simulations *ab initio* and *classic*, this study investigates the classical version. The classical MD concept stands on famous Newton's equation $F = ma$. We just solve this equation with applied mathematical concepts.

$$\vec{F} = m \vec{a} = m \frac{d^2 \vec{r}}{dt^2} \quad (1)$$

2 Simulation Methodology

Though the classical MD sounds pretty simple as it requires to solve $F = ma$ but the algorithmic methods developed to attain this simple problem are interesting.

2.1 Initial velocity with Box-Muller

In the Box-Muller method random numbers are used between $[0,1]$. Two random numbers x_1 and x_2 are generated. They are used in below equations to calculate velocity.

$$v_1 = \sqrt{-2\ln x_1} \cos(2\pi x_2) \quad (2)$$

$$v_2 = \sqrt{-2\ln x_2} \sin(2\pi x_1) \quad (3)$$

Velocities can be chosen using Maxwell-Boltzmann distribution

$$P(\vec{v}) = \left(\frac{m}{2\pi k_B T}\right)^{\frac{3}{2}} \exp\left[-\frac{m(v_x^2 + v_y^2 + v_z^2)}{2k_B T}\right] \quad (4)$$

2.2 Lennard Jones potential

The interatomic potential between two particle is calculated using Lennard Jones pair potential. The minimum distance between atoms are set by $r_{min} = 2^{\frac{1}{6}}\sigma$ and depth of the minimum as $-\epsilon$. All parameters are scaled as $m = 1, \sigma = 1, \epsilon = 1$. Again one unit of time scale for this problem is $\tau = (\frac{m\sigma^2}{\epsilon}) = 2.17ps$. So, the simulation is executed for $4.34ps$ to observe steady state effect with a time step of $2.17fs$.

$$V(r) = 4\epsilon\left[\left(\frac{\sigma}{r}\right)^{12} - \left(\frac{\sigma}{r}\right)^6\right] \quad (5)$$

The Force is calculated as:

$$\vec{F}(r) = -\frac{\partial V}{\partial r} \hat{r} \quad (6)$$

2.3 The Verlet algorithm

The Verlet algorithm solves the differential form of velocity and acceleration with numerical approach. Finite difference methods can be used for the purpose. As in central difference method the correction term, $O(\delta t)^2$ is of higher order than forward and backward difference method, $O(\delta t)$, the central difference formula is employed to develop Verlet equations to calculate velocity and displacement:

$$\vec{v}_i(t + \delta t) = \vec{v}_i(t) + \frac{1}{2}\delta t(\vec{a}_i(t + \delta t) + \vec{a}_i(t)) \quad (7)$$

$$\vec{x}_i(t + \delta t) = \vec{x}_i(t) + \delta t\vec{v}_i(t) + \frac{1}{2}\delta t^2\vec{F}_i(t)/m_i \quad (8)$$

The temperature correction of velocity is performed according to below formula to check the run away of the particles.

$$\vec{v}_{new} = \vec{v}_i \sqrt{\frac{T_{goal}}{T_{simulated}}} \quad (9)$$

3 Results

The classical Molecular Dynamics simulation is implemented in Python and Fortran. The FCC lattice generation part is done in Python then Fortran is used for all the calculations. Again Python is used to generate all the plots. Fortran is used for velocity initialization to final energy and lattice position calculations. Code is available in github at https://github.com/tridip66/molecular_dynamics/tree/master/src. The simulation tries to keep the temperature constant, so steady kinetic energy is observed. The total energy of the system fluctuates around a steady state. It can be observed in the Figure 1 which is run for 10ps at $T = 1$. For visualization of crystal lattice VESTA has been used.

It can be observed that the fluctuations are subsided in Figure 2, when the target temperature is low $T = 0.1$.

The temperature fluctuation with simulation time is shown in Figure 3. The goal for temperature was set at $T = 1.0$. The temperature varies nicely around the goal.

During the simulation of the FCC lattice it was possible that due to resultant velocity of all the particles the simulation box may get some momentum. Hence, a correction has been applied for the velocity to keep the momentum of the center of mass negligible. The momentum of the center mass with time is shown in Figure 4 at high temperature $T = 1.0$, when the velocity fluctuation is higher. As the velocity fluctuation for every particle can be interesting phenomena to observe and it can give an idea of melting when translated to displacement, so the velocity fluctuations of five particles are plotted in Figure 5. Velocity variation with time is not plotted for all the particles as it will make the plot clumsy.

3.1 Visualization of Melting

The final position of the atoms in the crystal lattice are recorded after a 4.34 ps of simulation run. As the time is sufficient to reach the steady temperature for the system. In Figure 6 final atom positions are displayed for four different temperatures ($T = 0.0, 0.1, 0.5, 1.0$). At temperature $T = 0.5$ it is clear that lattice vibration increases and at $T = 1.0$ the periodicity of the system is lost.

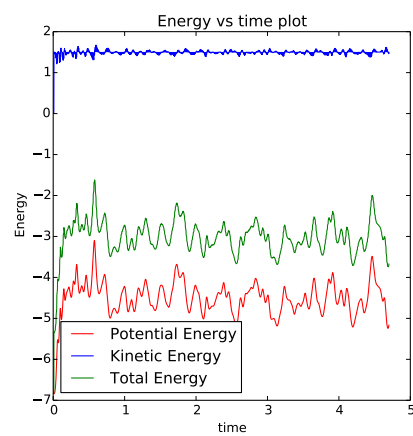

Figure 1: Energy vs time plot at $T = 1.0$ for 10 ps of simulation performed

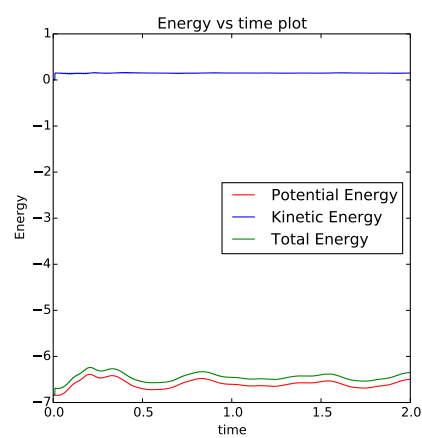

Figure 2: Energy vs time plot at $T = 0.1$ for 4.34 ps of simulation

Figure 3: Temperature fluctuation around $T = 1.0$ with time calculated at $T = 1.0$

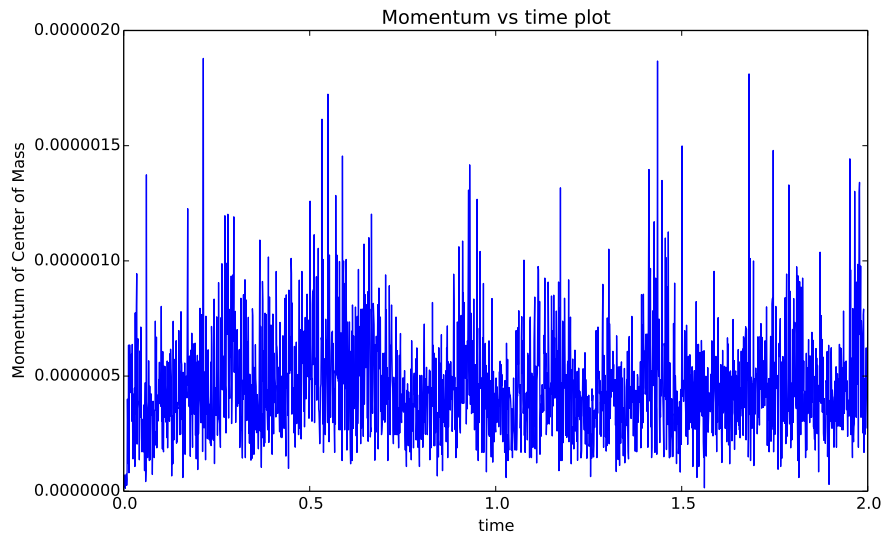

Figure 4: Momentum of the center of mass with time at $T = 1.0$

This can be assumed as melting of the structure. VESTA is used for the visualization of the structures. For better capturing of melting root mean square displacement can be plotted at different temperature. Also, from coordination number decreament with increasing temperature can find the melting point.
